Abstract

Vacuum expectation value of the surface energy-momentum tensor is evaluated for a massive scalar field with general curvature coupling parameter subject to Robin boundary conditions on two parallel branes located on $(D+1)$-dimensional AdS bulk. The general case of different Robin coefficients on separate branes is considered. As an regularization procedure the generalized zeta function technique is used, in combination with contour integral representations. The surface energies on the branes are presented in the form of the sums of single brane and second brane-induced parts. For the geometry of a single brane both regions, on the left (L-region) and on the right (R-region), of the brane are considered. The surface densities for separate L- and R-regions contain pole and finite contributions. For an infinitely thin brane taking these regions together, in odd spatial dimensions the pole parts cancel and the total surface energy is finite. The parts in the surface densities generated by the presence of the second brane are finite for all nonzero values of the interbrane separation. It is shown that for large distances between the branes the induced surface densities give rise to an exponentially suppressed cosmological constant on the brane. In the Randall-Sundrum braneworld model, for the interbrane distances solving the hierarchy problem between the gravitational and electroweak mass scales, the cosmological constant generated on the visible brane is of the right order of magnitude with the value suggested by the cosmological observations.

1 Introduction

The dynamics of fields on anti-de Sitter (AdS) background possesses remarkable properties and much of early interest to this spacetime was motivated by the questions of principal nature related to the quantization of fields propagating on curved backgrounds. The presence of the both regular and irregular modes and the possibility of interesting causal structure lead to many new phenomena. The importance of this theoretical work increased when it has been discovered that AdS spacetime generically arises as ground state in extended supergravity and in string theories. Further interest in this subject was, and continues to be, generated by the

appearance of two models where AdS geometry plays a special role. The first model, the so called AdS/CFT correspondence, was motivated by Maldacena [1] (for a review see [2]) and represents a realization of the holographic principle. The AdS/CFT correspondence relates string theories or supergravity in the bulk of AdS with a conformal field theory living on its boundary. It has many interesting formal and physical facets and provides a powerful tool to investigate gauge field theories, in particular QCD. The second model, suggested by Randall and Sundrum [3],[4], is a realization of a braneworld scenario with large extra dimensions. Recently it has been realized that the introduction of large extra spatial dimensions may provide a solution to the hierarchy problem between the gravitational and electroweak mass scales [5] (for reviews in braneworld gravity and cosmology see Refs. [6]-[8]). The main idea to resolve the large hierarchy is that the small coupling of four dimensional gravity is generated by the large physical volume of extra dimensions. Braneworlds naturally appear in string/M-theory context and provide a novel setting for discussing phenomenological and cosmological issues related to extra dimensions. The model introduced by Randall and Sundrum is particularly attractive. Their background solution consists of two parallel flat branes, one with positive tension and another with negative tension embedded in a five dimensional AdS bulk [3]. The fifth coordinate is compactified on S^1/Z_2, and the branes are on the two fixed points. It is assumed that all matter fields are confined on the branes and only the gravity propagates freely in the five dimensional bulk. In this model, the hierarchy problem is solved if the distance between the branes is about 37 times the AdS radius and we live on the negative tension brane. More recently, alternatives to confining particles on the brane have been investigated and scenarios with additional bulk fields have been considered [9],[10]. Apart from the hierarchy problem it has been also tried to solve the cosmological constant problem within the braneworld scenario. The problem of the cosmological constant has been considered as the most serious mass hierarchy problem in modern particle physics (see, for instance, [11]) and many attempts addressing this fine-tuning issue can be found in the literature. The braneworld theories may give some alternative discussion of the cosmological constant (see Refs. [12] and references therein). The basic new ingredient is that the vacuum energy generated by quantum fluctuations of fields living on the brane may not curve the brane itself but instead the space transverse to it.

The investigation of quantum effects in braneworld models is of considerable phenomenological interest, both in particle physics and in cosmology. The braneworld corresponds to a manifold with dynamical boundaries and all fields which propagate in the bulk will give Casimir-type contributions to the vacuum energy (for reviews of the Casimir effect see Refs. [13],[14]), and as a result to the vacuum forces acting on the branes. In dependence of the type of a field and boundary conditions imposed, these forces can either stabilize or destabilize the braneworld. In addition, the Casimir energy gives a contribution to both the brane and bulk cosmological constants and, hence, has to be taken into account in the self-consistent formulation of the braneworld dynamics. Motivated by these, the role of quantum effects in braneworld scenarios has received a great deal of attention. For a conformally coupled scalar this effect was initially studied in Ref. [15] in the context of M-theory, and subsequently in Refs. [16]-[31] for a background Randall–Sundrum geometry (for the related heat kernel expansions see Refs. [32]). The models with dS and AdS branes, and higher dimensional brane models are considered as well [28],[33]-[40]. For a conformally cupled bulk scalar the cosmological backreaction of the Casimir energy is investigated in Refs. [15],[28],[33],[41]-[43].

In the papers mentioned above, the authors consider mainly the global quantities such as the total Casimir energy or conformally invariant fields. The investigation of local physical characteristics in the Casimir effect, such as expectation value of the energy-momentum tensor, is of considerable interest. In addition to describing the physical structure of the quantum field at a given point, the energy-momentum tensor acts as the source in the Einstein equations and therefore plays an important role in modelling a self-consistent dynamics involving the gravitational field. In the case of two parallel branes on AdS background, the vacuum expectation value of the bulk energy-momentum tensor for a scalar field with an arbitrary curvature coupling is investigated in Refs. [30],[31]. In particular, in Ref. [31] the application of the generalized Abel-Plana formula [44] to the corresponding mode sums allowed us to extract manifestly the parts due to the AdS spacetime without boundaries and to present the boundary induced parts in terms of exponentially convergent integrals for the points away the boundaries. The interaction forces between the branes are investigated as well. Depending on the coefficients in the boundary conditions, these forces can be either attractive or repulsive. On the background of manifolds with boundaries, the physical quantities, in general, will receive both volume and surface contributions and the surface terms play an important role in various branches of physics. In particular, the surface counterterms introduced to renormalize the divergencies in the quasilocal definitions of the energy for the gravitational field and in quantum field theory with boundaries are of particular interest. For scalar fields with general curvature coupling, in Ref. [45] it has been shown that in the discussion of the relation between the mode sum energy, evaluated as the sum of the zero-point energies for each normal mode of frequency, and the volume integral of the renormalized energy density for the Robin parallel plates geometry it is necessary to include in the energy a surface term concentrated on the boundary (see also the discussion in Refs. [14],[46]). Similar issues for the spherical and cylindrical boundary geometries are discussed in Refs. [47],[48]. An expression for the surface energy-momentum tensor for a scalar field with a general curvature coupling parameter in the general case of bulk and boundary geometries is derived in Ref. [49]. The purpose of the present paper is to study the vacuum expectation value of this tensor for a scalar field obeying Robin boundary conditions on a single and two parallel branes of codimension one in $(D+1)$-dimensional AdS spacetime. In particular, we show that in the two-brane set up the surface densities induced on a brane by the presence of the second brane are exponentially small for large interbrane distances and give rise to naturally suppressed cosmological constant in the brane universe.

The paper is organized as follows. In the next section we show that the vacuum expectation value of the surface energy momentum tensor can be expressed via the expectation values of the field square evaluated on the branes. By using the Cauchiy's theorem on residues, an integral representations for the related zeta functions for both branes are constructed. They contain parts due to a single brane when the second brane is absent, and parts which are induced by the presence of the second brane. The latters are finite at the physical point. The analytic continuation for single plate contributions is constructed in Section 3 for both regions, on the right and on the left of the brane. The surface densities for two-branes geometry are investigated in Section 4. Various limiting cases are considered and the cosmological constant induced on the brane is estimated. In Section 5 we discuss the balance between the separate parts of the vacuum energy and show that they satisfy standard thermodynamic relation. The last section contains a summary of the work.

2 Surface energy-momentum tensor and the generalized zeta function

In this paper we consider a massive scalar field $\varphi(x)$ on background of a $(D+1)$-dimensional AdS spacetime (AdS_{D+1}) with the line element

$$ds^2 = g_{ik}dx^i dx^k = e^{-2k_D y}\eta_{\mu\nu}dx^\mu dx^\nu - dy^2, \tag{2.1}$$

and AdS radius given by $1/k_D$. Here $\eta_{\mu\nu} = \mathrm{diag}(1, -1, \ldots, -1)$ is the metric for the D-dimensional Minkowski spacetime, $i, k = 0, 1, \ldots, D$, and $\mu, \nu = 0, 1, \ldots, D-1$. The corresponding field equation reads

$$\left(g^{ik}\nabla_i\nabla_k + m^2 + \zeta R\right)\varphi(x) = 0, \tag{2.2}$$

where the symbol ∇_i is the operator for the covariant derivative associated with the metric g_{ik}, $R = -D(D+1)k_D^2$ is the corresponding Ricci scalar, and ζ is the curvature coupling parameter. For minimally and conformally coupled scalars one has $\zeta = 0$ and $\zeta = \zeta_c = (D-1)/4D$ correspondingly. Note that by making a coordinate transformation

$$z = e^{k_D y}/k_D, \tag{2.3}$$

metric (2.1) is written in a manifestly conformally-flat form $ds^2 = (k_D z)^{-2}\eta_{ik}dx^i dx^k$ with $x^D = z$. This is the AdS_{D+1} line element in Poincaré coordinates.

Below we will assume that the field obeys mixed boundary conditions on two parallel infinite plane boundaries (branes), located at $y = a$ and $y = b$, $a < b$:

$$\left(\tilde{A}_y + \tilde{B}_y\partial_y\right)\varphi(x) = 0, \quad y = a, b, \tag{2.4}$$

with constant coefficients $\tilde{A}_y$, $\tilde{B}_y$. This type of boundary conditions naturally arises for bulk fields in the Randall-Sundrum braneworld due to the Z_2 symmetry of the model. The presence of boundaries modifies the spectrum for the zero–point fluctuations of the scalar field under consideration. This leads to the modification of the vacuum expectation values of physical quantities to compared with the case without boundaries. For the geometry under consideration, the Wightman function and the corresponding vacuum expectation value of the bulk energy-momentum tensor are investigated in Ref. [31] (see also Ref. [27] for the case of a conformally invariant scalar field). The energy-momentum tensor for a scalar field on manifolds with boundaries in addition to the bulk part contains a contribution located on the boundary. For an arbitrary smooth boundary ∂M_s with the inward-pointing unit normal vector n^l, the surface part of the energy-momentum tensor is given by the formula [49]

$$T_{ik}^{(\rm surf)} = \delta(x;\partial M_s)\tau_{ik} \tag{2.5}$$

with

$$\tau_{ik} = \zeta\varphi^2 K_{ik} - (2\zeta - 1/2)h_{ik}\varphi n^l\nabla_l\varphi, \tag{2.6}$$

and the "one-sided" delta-function $\delta(x;\partial M_s)$ locates this tensor on ∂M_s. In Eq. (2.6), $K_{ik} = h_i^l h_k^m \nabla_l n_m$ is the extrinsic curvature tensor of the boundary ∂M_s and $h_{ik} = g_{ik} + n_i n_k$ is the corresponding induced metric. Here we are interested in the vacuum expectation values of the surface energy-momentum tensor (2.5) on the branes $y = a$ and $y = b$.

Let $\{\varphi_\alpha(x), \varphi_\alpha^*(x)\}$ be a complete set of positive and negative frequency solutions to the field equation (2.2), obeying the boundary condition (2.4). Here α is a collective index for all quantum numbers. By expanding the field operator over the eigenfunctions $\varphi_\alpha(x)$, using the standard commutation rules and the definition of the vacuum state, for the vacuum expectation value of the surface energy-momentum tensor one finds

$$\langle 0|T_{ik}^{(\rm surf)}|0\rangle = \delta(x;\partial M_s)\langle 0|\tau_{ik}|0\rangle, \tag{2.7}$$

where

$$\langle 0|\tau_{ik}|0\rangle = \sum_\alpha \tau_{ik}\{\varphi_\alpha(x), \varphi_\alpha^*(x)\}. \tag{2.8}$$

Here $|0\rangle$ is the amplitude for the corresponding vacuum state, and the bilinear form $\tau_{ik}\{\varphi,\psi\}$ on the right of the second formula is determined by the classical energy-momentum tensor (2.6). For the geometry of two parallel branes on AdS bulk one has ($j=a,b$)

$$\begin{aligned} n^{(j)l} &= n^{(j)}\delta_D^l, \quad n^{(a)}=1, \quad n^{(b)}=-1, \\ K_{\mu\nu}^{(j)} &= -n^{(j)}k_D g_{\mu\nu}, \quad \mu,\nu=0,1,\ldots,D-1, \end{aligned} \tag{2.9}$$

and $K_{DD}^{(j)}=0$, where $n^{(j)l}$ and $K_{ik}^{(j)}$ are the inward-pointing unit normal and the extrinsic curvature tensor for the brane at $y=j$, $j=a,b$ (we consider the region between the branes, $a\leq y\leq b$). Note that boundary conditions (2.4) can be written in the covariant form $(\tilde{A}_j+n^{(j)}\tilde{B}_j n^{(j)l}\nabla_l)\varphi=0$. By using relations (2.9) and the boundary conditions, the vacuum expectation value of the surface energy-momentum tensor on the brane at $y=j$ is presented in the form

$$\langle 0|\tau_{\mu\nu}^{(j)}|0\rangle = -g_{\mu\nu}n^{(j)}\left[\zeta k_D-(2\zeta-1/2)\tilde{A}_j/\tilde{B}_j\right]\langle 0|\varphi^2|0\rangle_{z=z_j}, \tag{2.10}$$

and $\langle 0|\tau_{DD}^{(j)}|0\rangle=0$. From the point of view of physics on the brane, Eq. (2.10) corresponds to the gravitational source of the cosmological constant type,

$$\langle 0|\tau_{\mu}^{(j)\nu}|0\rangle = \mathrm{diag}\left(\varepsilon_j^{(\mathrm{surf})},-p_j^{(\mathrm{surf})},\ldots,-p_j^{(\mathrm{surf})}\right), \tag{2.11}$$

with the surface energy density $\varepsilon_j^{(\mathrm{surf})}$ (surface energy per unit physical volume on the brane at $z=z_j$ or brane tension), stress $p_j^{(\mathrm{surf})}$ and the equation of state

$$\varepsilon_j^{(\mathrm{surf})}=-p_j^{(\mathrm{surf})}. \tag{2.12}$$

Of course, this is the direct consequence of the Poincaré invariance of the branes.

For an untwisted bulk scalar in the $(D+1)$-dimensional version of the Randall-Sundrum braneworld with brane mass terms c_a and c_b, the ratio of the coefficients in the boundary condition (2.4) is determined by the expression (see, e.g., Refs. [9],[24],[31])

$$\frac{\tilde{A}_j}{\tilde{B}_j}=-\frac{n^{(j)}c_j+4D\zeta k_D}{2}. \tag{2.13}$$

For the coefficient in formula (2.10) this gives

$$2\zeta-(4\zeta-1)\frac{\tilde{A}_j}{k_D\tilde{B}_j}=8D\zeta(\zeta-\zeta_c)+(4\zeta-1)\,n^{(j)}\frac{c_j}{2k_D}. \tag{2.14}$$

In particular, the surface energy in the Randall-Sundrum braneworld vanishes for minimally and conformally coupled scalar fields with zero brane mass terms. Note that in the supersymmetric version of the model [9] one has $c_b=-c_a$.

AdS spacetime is divided by the branes into three regions with $y\leq a$, $a\leq y\leq b$, and $y\geq b$. Below in this section, we will consider the region between the branes. The corresponding quantities for the other regions are obtained from those as limiting cases and are investigated in the next section. Note that in a S^1/Z_2 version of the model, the only bulk is between the branes. Due to the D-dimensional Poincaré invariance, the corresponding eigenfunctions can be presented in the form

$$\begin{aligned} \varphi_\alpha(x) &= \frac{f_u(y)e^{-i\eta_{\mu\nu}k^\mu x^\nu}}{\sqrt{2\omega(2\pi)^{D-1}}}, \quad k^\mu=(\omega,\mathbf{k}), \\ \omega &= \sqrt{k^2+u^2}, \quad k=|\mathbf{k}|. \end{aligned} \tag{2.15}$$

Here the separation constants u are determined by boundary conditions (2.4) and will be given below. Substituting eigenfunctions (2.15) into the field equation (2.2), one obtains the equation for the function $f_u(y)$ with the solution

$$f_u(y) = C_\alpha e^{Dk_D y/2} \left[J_\nu(uz) + b_\nu Y_\nu(uz) \right], \tag{2.16}$$

in the region $a \leq y \leq b$. Here $J_\nu(x)$, $Y_\nu(x)$ are the Bessel and Neumann functions of the order

$$\nu = \sqrt{(D/2)^2 - D(D+1)\zeta + m^2/k_D^2}. \tag{2.17}$$

The parameter ν must be real to ensure stability [50],[51]. For a given ζ this imposes a lower bound for the mass (Breitenlohner-Freedman bound). Note that on AdS bulk the parameter m^2 can be negative. In the case of a conformally coupled massless scalar, $\zeta = \zeta_c$, one has $\nu = 1/2$ and the cylinder functions in Eq. (2.16) are expressed via the elementary functions.

In the region between the branes, the coefficient b_ν is determined from the boundary condition on $y = a$:

$$b_\nu = -\frac{\bar{J}_\nu^{(a)}(uz_a)}{\bar{Y}_\nu^{(a)}(uz_a)}, \quad z_j = \frac{e^{k_D j}}{k_D}, \quad j = a, b\,. \tag{2.18}$$

Here and below we use the barred notation

$$\bar{F}^{(j)}(x) = A_j F(x) + B_j x F'(x), \tag{2.19}$$

for a given function $F(x)$, with the coefficients

$$A_j = \tilde{A}_j + \tilde{B}_j k_D D/2, \quad B_j = \tilde{B}_j k_D. \tag{2.20}$$

Note that for a bulk scalar field in the Randall-Sundrum model from Eq. (2.13) one has $2A_j/B_j = D(1-4\zeta) - n^{(j)} c_j/k_D$. From the boundary condition on the brane $y = b$ we receive that the eigenvalues for u have to be solutions to the equation

$$g_\nu^{(ab)}(uz_a, uz_b) \equiv \bar{J}_\nu^{(a)}(uz_a)\bar{Y}_\nu^{(b)}(uz_b) - \bar{Y}_\nu^{(a)}(uz_a)\bar{J}_\nu^{(b)}(uz_b) = 0. \tag{2.21}$$

This equation gives the spectrum of Kaluza-Klein masses. We denote by $u = u_{\nu,n}$, $n = 1, 2, \ldots$, the zeros of the function $g_\nu^{(ab)}(uz_a, uz_b)$ in the right half-plane of the complex variable u, arranged in the ascending order, $u_{\nu,n} < u_{\nu,n+1}$. The set of quantum numbers specifying the eigenfunctions is $\alpha = (\mathbf{k}, n)$. In our analysis we will assume that the values A_j/B_j are such that there are no imaginary zeros. This is the case, for example, when $A_a/B_a \leq 0$ and $A_b/B_b \geq 0$ (see also Ref. [52]). The coefficient C_α in Eq. (2.16) is determined from the orthonormality condition

$$\int_a^b dy\, e^{(2-D)k_D y} f_{u_{\nu,n}}(y) f_{u_{\nu,n'}}(y) = \delta_{nn'}, \tag{2.22}$$

and is equal to

$$C_\alpha^2 = \frac{\pi}{k_D z_a} \frac{\bar{Y}_\nu^{(a)}(uz_a)\bar{Y}_\nu^{(b)}(uz_b)}{\frac{\partial}{\partial u} g_\nu^{(ab)}(uz_a, uz_b)}, \quad u = u_{\nu,n}. \tag{2.23}$$

As it follows from formula (2.10), the vacuum expectation values of the surface energy-momentum tensor can be obtained from the vacuum expectation values of the field square evaluated on the branes. Substituting the eigenfunctions (2.15) into the corresponding mode sum and integrating over the angular part of the vector $\mathbf{k}$, for the expectation value of the field square in the region between the branes one finds

$$\begin{aligned}\langle 0|\varphi^2(x)|0\rangle &= \sum_\alpha \varphi_\alpha(x)\varphi_\alpha^*(x) \\ &= \pi k_D^{D-1} z^D \beta_D \int_0^\infty dk \sum_{n=1}^\infty \frac{k^{D-2} u_{\nu,n} \prod_{j=a,b} g_\nu^{(j)}(u_{\nu,n} z_j, u_{\nu,n} z)}{\sqrt{u_{\nu,n}^2+k^2}\, \frac{\partial}{\partial u} g_\nu^{(ab)}(u z_a, u z_b)\Big|_{u=u_{\nu,n}}}, \end{aligned} \tag{2.24}$$

where we have introduced the notations

$$\beta_D = \frac{1}{(4\pi)^{\frac{D-1}{2}} \Gamma\left(\frac{D-1}{2}\right)}, \tag{2.25}$$

and

$$g_\nu^{(j)}(u,v) = J_\nu(v) \bar{Y}_\nu^{(j)}(u) - Y_\nu(v) \bar{J}_\nu^{(j)}(u). \tag{2.26}$$

By using the relation $g_\nu^{(j)}(u,u) = 2B_j/\pi$, for the corresponding vacuum expectation value on the brane at $y = j$ we obtain

$$\langle 0|\varphi^2(x)|0\rangle_{z=z_j} = 2 k_D^{D-1} z_j^D B_j \beta_D \int_0^\infty dk\, k^{D-2} \sum_{n=1}^\infty \frac{u_{\nu,n} g_\nu^{(l)}(u_{\nu,n} z_l, u_{\nu,n} z_j)}{\sqrt{u_{\nu,n}^2+k^2}\, \frac{\partial}{\partial u} g_\nu^{(ab)}(u z_a, u z_b)\Big|_{u=u_{\nu,n}}}, \tag{2.27}$$

where $j, l = a, b$, and $l \neq j$. Quantity (2.27) and, hence, the surface energy-momentum tensor diverge and need some regularization. Many regularization techniques are available nowadays and, depending on the specific physical problem under consideration, one of them may be more suitable than the others. In particular, the generalized zeta function method [53],[54] is in general very powerful to give physical meaning to the divergent quantities. There are several examples of the application of this method to the evaluation of the Casimir effect (see, for instance, [54]-[57] and references therein). Here we will use the method which is an analog of the generalized zeta function approach.

Instead of (2.27) we define the function

$$F_j(s) = 2 k_D^{D-1} z_j^D \frac{B_j \beta_D}{\mu^{1+s}} \int_0^\infty dk\, k^{D-2} \sum_{n=1}^\infty (u_{\nu,n}^2 + k^2)^{s/2} \frac{u_{\nu,n} g_\nu^{(l)}(u_{\nu,n} z_l, u_{\nu,n} z_j)}{\frac{\partial}{\partial u} g_\nu^{(ab)}(u z_a, u z_b)|_{u=u_{\nu,n}}}, \tag{2.28}$$

with μ an arbitrary mass scale which has been introduced to keep the dimension of the expression. Evaluating the integral over k, this expression can be presented in the form

$$F_j(s) = k_D^{D-1} z_j^D \frac{B_j \beta_D}{\mu^{1+s}} B\left(\frac{D-1}{2}, -\frac{D-1+s}{2}\right) \zeta_j(s), \tag{2.29}$$

where $B(x,y)$ is the beta function and we have defined the generalized zeta function as

$$\zeta_j(s) = \sum_{n=1}^\infty \frac{u_{\nu,n}^{D+s} g_\nu^{(l)}(u_{\nu,n} z_l, u_{\nu,n} z_j)}{\frac{\partial}{\partial u} g_\nu^{(ab)}(u z_a, u z_b)|_{u=u_{\nu,n}}}. \tag{2.30}$$

We could include in the definition of the zeta function an additional factor μ^{-D-s-2} to keep this function dimensionless. However, this will not affect on the final result for the analytic continuation of the function $F_j(s)$. The computation of vacuum expectation value of the surface energy-momentum tensor requires the analytic continuation of the function $F_j(s)$ to the value $s = -1$ (here and below $|_{s=-1}$ is understood in the sense of the analytic continuation),

$$\langle 0|\varphi^2|0\rangle_{z=z_j} = F_j(s)|_{s=-1}. \tag{2.31}$$

The starting point of our consideration is the representation of the function (2.30) in terms of contour integral:

$$\zeta_j(s)=\frac{1}{2\pi i}\int_C du\, u^{D+s}\frac{g_\nu^{(l)}(uz_l,uz_j)}{g_\nu^{(ab)}(uz_a,uz_b)}, \tag{2.32}$$

where C is a closed counterclockwise contour in the complex u plane enclosing all zeros $u_{\nu,n}$. The location of these zeros enables one to deform the contour C into a segment of the imaginary axis $(-iR,iR)$ and a semicircle of radius R, $R\to\infty$, in the right half-plane. We will also assume that the origin is avoided by the semicircle C_ρ in the right half-plane with small radius ρ. For sufficiently large s the integral over the large semicircle in Eq. (2.32) tends to zero in the limit $R\to\infty$, and the expression on the right can be transformed to

$$\begin{aligned}\zeta_j(s)=&\frac{1}{2\pi i}\int_{C_\rho} du\, u^{D+s}\frac{g_\nu^{(l)}(uz_l,uz_j)}{g_\nu^{(ab)}(uz_a,uz_b)}\\&+\frac{1}{\pi}\sin\frac{\pi}{2}(D+1+s)\int_\rho^\infty du\, u^{D+s}\frac{G_\nu^{(l)}(uz_l,uz_j)}{G_\nu^{(ab)}(uz_a,uz_b)},\end{aligned} \tag{2.33}$$

where $(j=a,b)$

$$G_\nu^{(j)}(u,v) = I_\nu(v)\bar{K}_\nu^{(j)}(u)-K_\nu(v)\bar{I}_\nu^{(j)}(u), \tag{2.34}$$

$$G_\nu^{(ab)}(u,v) = \bar{K}_\nu^{(a)}(u)\bar{I}_\nu^{(b)}(v)-\bar{I}_\nu^{(a)}(u)\bar{K}_\nu^{(b)}(v), \tag{2.35}$$

and we have introduced the Bessel modified functions $I_\nu(u)$ and $K_\nu(u)$. Below we will consider the limit $\rho\to 0$. In this limit the first integral on the right of formula (2.33) vanishes at the physical point $s=-1$, and we will concentrate on the contribution of the second integral. The corresponding expression can be presented in the form

$$\zeta_j(s)=-\frac{1}{\pi}\sin\frac{\pi}{2}(D+1+s)\int_\rho^\infty du\, u^{D+s}\left[n^{(j)}U_{j\nu}(uz_j)+B_j\Omega_{j\nu}(uz_a,uz_b)\right], \tag{2.36}$$

with the notations

$$U_{a\nu}(x)=\frac{K_\nu(x)}{\bar{K}_\nu^{(a)}(x)},\quad U_{b\nu}(x)=\frac{I_\nu(x)}{\bar{I}_\nu^{(b)}(x)} \tag{2.37}$$

and

$$\begin{aligned}\Omega_{a\nu}(u,v)&=\frac{\bar{K}_\nu^{(b)}(v)}{\bar{K}_\nu^{(a)}(u)G_\nu^{(ab)}(u,v)},\\ \Omega_{b\nu}(u,v)&=\frac{\bar{I}_\nu^{(a)}(u)}{\bar{I}_\nu^{(b)}(v)G_\nu^{(ab)}(u,v)}.\end{aligned} \tag{2.38}$$

Now by using the formula

$$B\left(\frac{D-1}{2},-\frac{D-1+s}{2}\right)\sin\frac{\pi}{2}(D+1+s)=\frac{\pi\Gamma\left(\frac{D-1}{2}\right)}{\Gamma\left(-\frac{s}{2}\right)\Gamma\left(\frac{D+1+s}{2}\right)}, \tag{2.39}$$

the corresponding expressions for the functions $F_j(s)$ can be rewritten in the form

$$F_j(s)=-\frac{(4\pi)^{\frac{1-D}{2}}k_D^{D-1}z_j^DB_j}{\Gamma\left(-\frac{s}{2}\right)\Gamma\left(\frac{D+1+s}{2}\right)\mu^{s+1}}\int_\rho^\infty du\, u^{D+s}\left[n^{(j)}U_{j\nu}(uz_j)+B_j\Omega_{j\nu}(uz_a,uz_b)\right]. \tag{2.40}$$

The contribution of the second term in the square brackets is finite at $s=-1$ and vanishes in the limits $z_a\to 0$ and $z_b\to\infty$. The first term in the square brackets of this expression corresponds to the contribution of a single brane at $z=z_j$ when the second brane is absent. The regularization is needed for this term only and the corresponding analytic continuation has been done in the next section.

3 Surface energy-momentum tensor for a single brane

The single brane at $z = z_a$ divides the AdS spacetime into two regions corresponding to $z < z_a$ (L-region) and $z > z_a$ (R-region). The properties of the vacuum in these regions are different and the corresponding quantities we will differ by the indices R (right) and L (left), respectively. Let us consider these regions separately.

3.1 L-region

From Eq. (2.40) it follows that for the geometry of a single brane located at $z = z_a$ the function $F_a(s) \equiv F_a^{(\mathrm{L})}(s)$ is determined by the expression

$$F_a^{(\mathrm{L})}(s) = \frac{(4\pi)^{\frac{1-D}{2}} k_D^{D-1} B_a}{\Gamma\left(-\frac{s}{2}\right)\Gamma\left(\frac{D+1+s}{2}\right)(\mu z_a)^{1+s}} \int_0^\infty du\, u^{D+s} \frac{I_\nu(u)}{\bar{I}_\nu^{(a)}(u)}. \tag{3.1}$$

This integral representation is valid in the strip $-(D+1) < \mathrm{Re}\, s < -D$ and under the assumption that the function $\bar{I}_\nu^{(a)}(u)$ has no real zeros. The latter corresponds to the absence of imaginary zeros for the eigenfunction $f_u(y)$ in Eq. (2.15) with respect to u. This condition is satisfied for $A_a/B_a \geq -\nu$. For the analytic continuation to $s = -1$, we write the integral on the right of this formula as the sum of the integrals over the intervals $(0, 1)$ and $(1, \infty)$. The first integral is finite at $s = -1$. To find an analytic continuation of the second integral we employ the asymptotic expansions of the Bessel modified function for large values of the argument (see, for instance, [58]). For $B_a \neq 0$ from these expansions one has

$$\frac{I_\nu(u)}{\bar{I}_\nu^{(a)}(u)} \sim \frac{1}{B_a} \sum_{l=0}^{\infty} \frac{w_l(\nu)}{u^{l+1}}, \tag{3.2}$$

where the coefficients $w_l(\nu)$ are combinations of the corresponding coefficients in the expansions for the functions $I_\nu(u)$ and $I_\nu'(u)$. The first four coefficients are as follows:

$$\begin{aligned} w_0(\nu) &= 1, \quad w_1(\nu) = \frac{1}{2} - \frac{A_a}{B_a}, \\ w_2(\nu) &= \frac{3}{8} - \frac{A_a}{B_a} + \frac{A_a^2}{B_a^2} - \frac{\nu^2}{2}, \\ w_3(\nu) &= \frac{3}{8} + \frac{3}{2}\frac{A_a^2}{B_a^2} - \frac{A_a^3}{B_a^3} + \frac{A_a}{B_a}\left(\nu^2 - 1\right) - \nu^2. \end{aligned} \tag{3.3}$$

Now we subtract and add to the integrand of the integral over $(1, \infty)$ the N leading terms of the corresponding asymptotic expansion and exactly integrate the asymptotic part. By this way Eq. (3.1) may be written in the form

$$\begin{aligned} F_a^{(\mathrm{L})}(s) =& \frac{(4\pi)^{\frac{1-D}{2}} k_D^{D-1} (\mu z_a)^{-1-s}}{\Gamma\left(-\frac{s}{2}\right)\Gamma\left(\frac{D+1+s}{2}\right)} \left\{ B_a \int_0^1 du\, u^{D+s} \frac{I_\nu(u)}{\bar{I}_\nu^{(a)}(u)} \right. \\ &\left. + \int_1^\infty du\, u^{D+s} \left[B_a \frac{I_\nu(u)}{\bar{I}_\nu^{(a)}(u)} - \sum_{l=0}^{N} \frac{w_l(\nu)}{u^{l+1}} \right] - \sum_{l=0}^{N} \frac{w_l(\nu)}{D+s-l} \right\}. \end{aligned} \tag{3.4}$$

For $N \geq D-1$ both integrals on the right are finite at $s = -1$ and $F_a^{(\mathrm{L})}(s)$ has a simple pole at $s = -1$ corresponding to the summand $l = D-1$ in the last sum. As a result, the expression for the vacuum expectation value for the field square on the brane contains pole and finite parts:

$$\langle 0|\varphi^2|0\rangle_{z=z_a}^{(\mathrm{L})} = \langle \varphi^2 \rangle_{z=z_a,\mathrm{p}}^{(\mathrm{L})} + \langle \varphi^2 \rangle_{z=z_a,\mathrm{f}}^{(\mathrm{L})}. \tag{3.5}$$

Laurent-expanding the expression on the right of Eq. (3.4) near $s=-1$, one finds

$$\langle\varphi^2\rangle^{(\mathrm{L})}_{z=z_a,\mathrm{p}} = -2k_D^{D-1}w_{D-1}(\nu)\frac{\beta_{D+1}}{s+1}, \tag{3.6}$$

for the pole part, and

$$\begin{aligned}\langle\varphi^2\rangle^{(\mathrm{L})}_{z=z_a,\mathrm{f}} =& 2k_D^{D-1}\beta_{D+1}\left\{B_a\int_0^1 du\,u^{D-1}\frac{I_\nu(u)}{\bar{I}_\nu^{(a)}(u)}\right.\\ &+\int_1^\infty du\,u^{D-1}\left[B_a\frac{I_\nu(u)}{\bar{I}_\nu^{(a)}(u)}-\sum_{l=0}^{N}\frac{w_l(\nu)}{u^{l+1}}\right]-\sum_{\substack{l=0\\ l\neq D-1}}^{N}\frac{w_l(\nu)}{D-l-1}\\ &\left.+\,w_{D-1}(\nu)\left[\ln(\mu z_a)+\frac{1}{2}\psi\left(\frac{D}{2}\right)-\frac{1}{2}\psi\left(\frac{1}{2}\right)\right]\right\},\end{aligned} \tag{3.7}$$

for the finite part, with $\psi(x)$ being the diagamma function. By using relations (2.10) and (3.5), we can write analogous decomposition for the surface energy density in the L-region:

$$\varepsilon_a^{(\mathrm{surf})(\mathrm{L})} = \varepsilon_{a,\mathrm{p}}^{(\mathrm{surf})(\mathrm{L})}+\varepsilon_{a,\mathrm{f}}^{(\mathrm{surf})(\mathrm{L})}, \tag{3.8}$$

$$\varepsilon_{a,\mathrm{s}}^{(\mathrm{surf})(\mathrm{L})} = \left[\zeta k_D-(2\zeta-1/2)\tilde{A}_a/\tilde{B}_a\right]\langle\varphi^2\rangle^{(\mathrm{L})}_{z=z_a,\mathrm{s}}, \tag{3.9}$$

with $\mathrm{s}=\mathrm{p},\mathrm{f}$, and for the surface stresses via the equation of state. Note that in the principal part prescription adopted in Ref. [57] (see also [54]) the Casimir energy corresponds to the principal part of the corresponding Laurent expansion near the physical point. In our case this is presented by the quantity $\varepsilon_{a,\mathrm{f}}^{(\mathrm{surf})(\mathrm{L})}$ ($\varepsilon_{a,\mathrm{f}}^{(\mathrm{surf})(\mathrm{R})}$ for the R-region, see below).

3.2 R-region

For a single brane at $z=z_a$ the function $F_a(s)\equiv F_a^{(\mathrm{R})}(s)$ in the R-region is determined from Eq. (2.40):

$$F_a^{(\mathrm{R})}(s) = -\frac{(4\pi)^{\frac{1-D}{2}}k_D^{D-1}B_a}{\Gamma\left(-\frac{s}{2}\right)\Gamma\left(\frac{D+1+s}{2}\right)(\mu z_a)^{1+s}}\int_0^\infty du\,u^{D+s}\frac{K_\nu(u)}{\bar{K}_\nu^{(a)}(u)}, \tag{3.10}$$

and differs from the corresponding function in the L-region by the replacement $I_\nu\to K_\nu$ (in general, the coefficients in the boundary condition could be different for the left and right surfaces of the brane). This integral representation is valid in the strip $-(D+1)<\mathrm{Re}\,s<-D$ and under the assumption of absence of real zeros for the function $\bar{K}_\nu^{(a)}(u)$. The latter is the case for $A_a/B_a\leq\nu$. The analytic continuation of the integral on the right to $s=-1$ can be found by the way similar to that for the L-region. For $B_a\neq 0$ the corresponding asymptotic expansion of the subintegrand for large values of the argument has the form

$$\frac{K_\nu(u)}{\bar{K}_\nu^{(a)}(u)}\sim-\frac{1}{B_a}\sum_{l=0}^{\infty}\frac{(-1)^l w_l(\nu)}{u^{l+1}}, \tag{3.11}$$

with the same coefficients $w_l(\nu)$ as in Eq. (3.2). Now Eq. (3.10) is written in the form

$$\begin{aligned}F_a^{(\mathrm{R})}(s) = &-\frac{(4\pi)^{\frac{1-D}{2}}k_D^{D-1}(\mu z_a)^{-1-s}}{\Gamma\left(-\frac{s}{2}\right)\Gamma\left(\frac{D+1+s}{2}\right)}\left\{B_a\int_0^1 du\,u^{D+s}\frac{K_\nu(u)}{\bar{K}_\nu^{(a)}(u)}\right.\\ &\left.+\int_1^\infty du\,u^{D+s}\left[B_a\frac{K_\nu(u)}{\bar{K}_\nu^{(a)}(u)}+\sum_{l=0}^{N}\frac{(-1)^l w_l(\nu)}{u^{l+1}}\right]+\sum_{l=0}^{N}\frac{(-1)^l w_l(\nu)}{D+s-l}\right\}.\end{aligned} \tag{3.12}$$

For $N \geq D-1$ the integrals on the right of this formula are finite at the point $s=-1$ and $F_a^{(\mathrm{R})}(s)$ has a simple pole at $s=-1$ presented by the summand $l=D-1$ in the last sum. Hence, the expression for the field square contains pole and finite parts:

$$\langle 0|\varphi^2|0\rangle^{(\mathrm{R})}_{z=z_a} = \langle\varphi^2\rangle^{(\mathrm{R})}_{z=z_a,\mathrm{p}} + \langle\varphi^2\rangle^{(\mathrm{R})}_{z=z_a,\mathrm{f}}, \tag{3.13}$$

where the separate contributions are obtained by Laurent-expanding expression (3.12) near the point $s=-1$:

$$\langle\varphi^2\rangle^{(\mathrm{R})}_{z=z_a,\mathrm{p}} = 2(-1)^D k_D^{D-1} w_{D-1}(\nu)\frac{\beta_{D+1}}{s+1}, \tag{3.14}$$

and

$$\begin{aligned}\langle\varphi^2\rangle^{(\mathrm{R})}_{z=z_a,\mathrm{f}} =& -2k_D^{D-1}\beta_{D+1}\left\{B_a\int_0^1 du\,u^{D-1}\frac{K_\nu(u)}{\bar{K}_\nu^{(a)}(u)}\right.\\ &+\int_1^\infty du\,u^{D-1}\left[B_a\frac{K_\nu(u)}{\bar{K}_\nu^{(a)}(u)}+\sum_{l=0}^{N}\frac{(-1)^l w_l(\nu)}{u^{l+1}}\right]+\sum_{\substack{l=0\\ l\neq D-1}}^{N}\frac{(-1)^l w_l(\nu)}{D-l-1}\\ &\left.+(-1)^D w_{D-1}(\nu)\left[\ln(\mu z_a)+\frac{1}{2}\psi\left(\frac{D}{2}\right)-\frac{1}{2}\psi\left(\frac{1}{2}\right)\right]\right\}.\end{aligned} \tag{3.15}$$

With the help of these formulae we obtain the similar decomposition for the surface energy density in the R-region:

$$\varepsilon_a^{(\mathrm{surf})(\mathrm{R})} = \varepsilon_{a,\mathrm{p}}^{(\mathrm{surf})(\mathrm{R})} + \varepsilon_{a,\mathrm{f}}^{(\mathrm{surf})(\mathrm{R})}, \tag{3.16}$$

$$\varepsilon_{a,\mathrm{s}}^{(\mathrm{surf})(\mathrm{R})} = -\left[\zeta k_D - (2\zeta - 1/2)\tilde{A}_a/\tilde{B}_a\right]\langle\varphi^2\rangle^{(\mathrm{R})}_{z=z_a,\mathrm{s}}, \tag{3.17}$$

with $\mathrm{s}=\mathrm{p},\mathrm{f}$. In the minimal subtraction scheme the pole term appearing in Eq. (3.16) is omitted. This corresponds to the principal part prescription of Ref. [57] for the total Casimir energy. Note that the structure of the pole terms in Eqs. (3.8) and (3.16) allows us to absorb them into the corresponding counterterms. There is the freedom to perform finite renormalizations since the renormalization counterterms shall be fixed by imposing some renormalization conditions (for the detailed discussion of the renormalization procedure for the vacuum energy in the Randall-Sundrum braneworld see Refs. [20, 22, 23]).

The total surface energy density for a single brane at $y=a$ is obtained by summing the contributions from the L- and R-regions:

$$\varepsilon_a^{(\mathrm{surf})(\mathrm{LR})} = \varepsilon_a^{(\mathrm{surf})(\mathrm{L})} + \varepsilon_a^{(\mathrm{surf})(\mathrm{R})}. \tag{3.18}$$

Now comparing the pole parts for the separate regions, we see that in odd spatial dimensions these parts cancel out. In particular, taking $N=D-1$, for the total surface energy density one obtains the formula

$$\begin{aligned}\varepsilon_a^{(\mathrm{surf})(\mathrm{LR})} =& k_D^D\beta_{D+1}\left[2\zeta B_a-(4\zeta-1)\tilde{A}_a\right]\left\{\int_0^1 du\,u^{D-1}\left[\frac{I_\nu(u)}{\bar{I}_\nu^{(a)}(u)}+\frac{K_\nu(u)}{\bar{K}_\nu^{(a)}(u)}\right]\right.\\ &+\int_1^\infty du\,u^{D-1}\left[\frac{I_\nu(u)}{\bar{I}_\nu^{(a)}(u)}+\frac{K_\nu(u)}{\bar{K}_\nu^{(a)}(u)}-\frac{2}{B_a}\sum_{l=0}^{\frac{D-3}{2}}\frac{w_{2l+1}(\nu)}{u^{2l+2}}\right]\\ &\left.-\frac{2}{B_a}\sum_{l=0}^{\frac{D-3}{2}}\frac{w_{2l+1}(\nu)}{D-2l-2}\right\},\end{aligned} \tag{3.19}$$

where the coefficients $w_l(\nu)$ are defined by relation (3.2). Note that this quantity does not depend on the renormalization scale μ and the position of the brane. In Fig. 1 we have plotted the surface energy density (3.19) as a function on the ratio A_a/B_a for massless minimally (left panel) and conformally (right panel) coupled scalar fields in $D=3$.

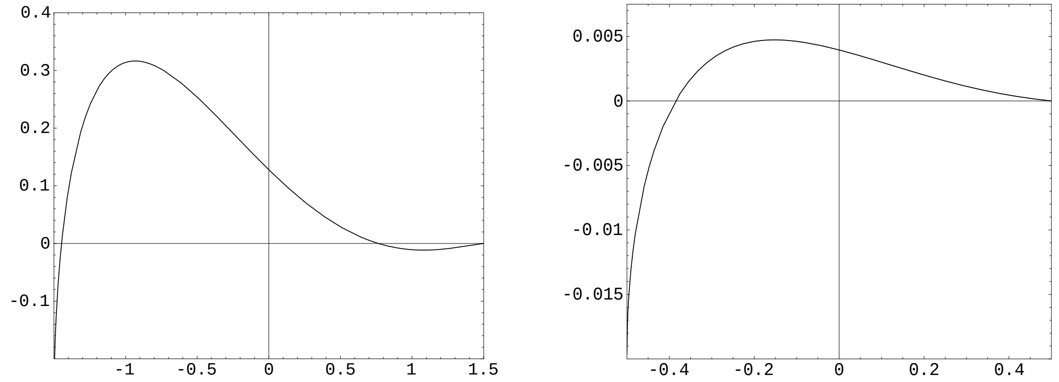

Figure 1: Surface energy density, $k_D^{-D}\varepsilon_a^{(\rm surf)}$ [see formula (3.19)], induced on a single plate as a function on the ratio A_a/B_a for massless minimally (left panel) and conformally (right panel) coupled scalar fields in $D=3$.

4 Surface densities for two-branes geometry and induced cosmological constant

In this section we investigate the surface densities generated on a brane by the presence of the second brane. These quantities are finite for all nonzero values of the interbrane separation and are not affected by finite renormalizations. Below we will concentrate on the energy densities as the corresponding stresses on the branes are directly obtained from the equation of state (2.12). On the base of relation (2.40), for the region $z_a \leq z \leq z_b$ the vacuum expectation value of the field square on the brane at $y=j$ ($j=a,b$) can be presented in the form

$$\langle 0|\varphi^2(x)|0\rangle_{z=z_j} = \langle 0|\varphi^2(x)|0\rangle^{(\rm J)}_{z=z_j} - 2k_D^{D-1}z_j^D B_j^2 \beta_{D+1}\int_0^\infty du\, u^{D-1}\Omega_{j\nu}(uz_a,uz_b), \tag{4.1}$$

where $\langle 0|\varphi^2(x)|0\rangle^{(\rm J)}_{z=z_j}$ is the corresponding quantity for a single brane at $y=j$ when the second brane is absent, $\rm J=R$ for $j=a$ and $\rm J=L$ for $j=b$. The second term on the right of Eq. (4.1) may also be obtained by using the expression for the corresponding Wightman function derived in Ref. [31] in the coincidence limit and evaluating its value on the branes. With the help of formulae (2.10), (4.1), the surface energy density on the brane at $z=z_j$ is presented as the sum

$$\varepsilon_j^{(\rm surf)} = \varepsilon_j^{(\rm surf)(J)} + \Delta\varepsilon_j^{(\rm surf)}, \tag{4.2}$$

where $\varepsilon_j^{(\rm surf)(J)}$ is the surface energy density induced on the corresponding surface of a single brane at $y=j$ when the second brane is absent (see previous section), and the term

$$\Delta\varepsilon_j^{(\rm surf)} = \left[2\zeta B_j - (4\zeta-1)\,\tilde{A}_j\right] n^{(j)}(k_D z_j)^D B_j \beta_{D+1}\int_0^\infty du\, u^{D-1}\Omega_{j\nu}(uz_a,uz_b) \tag{4.3}$$

is the energy density induced by the presence of the second brane. Note that this part is located on the surface $z=z_a+0$ for the brane at $z=z_a$ and on the surface $z=z_b-0$ for the brane at

$z = z_b$. On the surfaces $z = z_a - 0$ and $z = z_b + 0$ the surface densities are the same as for single branes. The expression on the right of Eq. (4.3) is finite for all values $z_a < z_b$ and is a function on the ratio z_b/z_a only. Note that this ratio is related to the interbrane distance by the formula

$$z_b/z_a = e^{k_D(b-a)}. \tag{4.4}$$

The main contribution into the integral in Eq. (4.3) comes from the modes with $u \lesssim (z_b - z_a)^{-1}$ and the contribution of higher modes is exponentially suppressed. Due to this suppression, the same results for the induced densities will be obrained in the model where instead of externally imposed boundary condition the fluctuating field is coupled to a smooth background potential that implements the boundary condition in a certain limit [59].

Using the Wronskian for the Bessel modified functions, it can be seen that

$$\left[B_j^2(x^2 z_j^2 + \nu^2) - A_j^2\right] \Omega_{j\nu}(xz_a, xz_b) = n^{(j)} z_j \frac{\partial}{\partial z_j} \ln \left| 1 - \frac{\bar{I}_\nu^{(a)}(xz_a)\bar{K}_\nu^{(b)}(xz_b)}{\bar{I}_\nu^{(b)}(xz_b)\bar{K}_\nu^{(a)}(xz_a)} \right|, \tag{4.5}$$

for $j = a, b$. This allows us to write the expression (4.3) for the surface energy density in another equivalent form:

$$\begin{aligned}\Delta\varepsilon_j^{(\text{surf})} =& k_D^D z_j^{D+1} B_j \beta_{D+1} \int_0^\infty du\, u^{D-1} \frac{2\zeta B_j + (1-4\zeta)\tilde{A}_j}{B_j^2(u^2 z_j^2 + \nu^2) - A_j^2} \\ & \times \frac{\partial}{\partial z_j} \ln \left| 1 - \frac{\bar{I}_\nu^{(a)}(uz_a)\bar{K}_\nu^{(b)}(uz_b)}{\bar{I}_\nu^{(b)}(uz_b)\bar{K}_\nu^{(a)}(uz_a)} \right|.\end{aligned} \tag{4.6}$$

This form of the surface energy density will be used below in the discussion of the energy balance.

Let us consider the limiting cases of the part (4.3). For large values of AdS radius to compared with the interbrane distance, $k_D(b-a) \ll 1$, the main contribution to the integral on the right of Eq. (4.3) comes from the large values of $uz_a \sim [k_D(b-a)]^{-1}$. Assuming that $\tilde{B}_a/(b-a)$ and $m(b-a)$ are fixed we see that the order of the Bessel modified functions is large. Replacing these functions by their uniform asymptotic expansions for large values of the order (see [58]), one obtains

$$\Delta\varepsilon_j^{(\text{surf})} \approx 2n^{(j)}(1-4\zeta)\tilde{A}_j \tilde{B}_j \beta_{D+1} \int_m^\infty du \frac{u^2(u^2 - m^2)^{\frac{D}{2}-1}(\tilde{A}_j^2 - \tilde{B}_j^2 u^2)^{-1}}{\frac{(\tilde{A}_a - \tilde{B}_a u)(\tilde{A}_b + \tilde{B}_b u)}{(\tilde{A}_a + \tilde{B}_a u)(\tilde{A}_b - \tilde{B}_b u)} e^{2u(b-a)} - 1}. \tag{4.7}$$

The expression on the right is the corresponding surface energy for two parallel Robin plates in the Minkowski spacetime. It can be easily checked that for a massless scalar field the sum $\Delta\varepsilon_a^{(\text{surf})} + \Delta\varepsilon_b^{(\text{surf})}$ evaluated from Eq. (4.7) coincides with the result obtained in Ref. [45]. In the limit of small interbrane separation, $(b-a) \to 0$, for a fixed k_D, by using the asymptotic formulae for the Bessel modified functions for large values of the argument, from the general formula in $D > 2$ dimensions we find

$$\Delta\varepsilon_j^{(\text{surf})} \approx -\left[2\zeta - (4\zeta - 1)\tilde{A}_j/B_j\right] \frac{n^{(j)}\sigma_j k_D \zeta_R(D-1)\Gamma\left(\frac{D+1}{2}\right)}{2^{D-1}\pi^{\frac{D+1}{2}}(D-1)(b-a)^{D-1}}, \tag{4.8}$$

where $\zeta_R(x)$ is the Riemann zeta function, $\sigma_j = 1$ for $|B_a/A_a|, |B_b/A_b| \gg k_D(b-a)$, and $\sigma_j = 2^{2-D} - 1$ for $|B_j/A_j| \gg k_D(b-a)$ and $B_l/A_l = 0$, with $l = b$ for $j = a$ and $l = a$ for $j = b$. We see that for small interbrane distances the sign of the induced surface energy density is determined by the factor $\left[2\zeta - (4\zeta - 1)\tilde{A}_j/B_j\right]$ and this sign is different for two cases of σ_j.

Now we turn to the asymptotic behavior of the surface energy density (4.3) for large distances between the branes, $k_D(b-a) \gg 1$. Introducing a new integration variable $x = uz_b$, by making use of formulae for the Bessel modified functions for small values of the argument, and assuming $|A_a| \neq |B_a|\nu$, to the leading order we receive

$$\Delta\varepsilon_a^{(\mathrm{surf})} \approx \left(\frac{z_a}{2z_b}\right)^{D+2\nu} \frac{4k_D^D B_a \left[2\zeta B_a - (4\zeta - 1)\,\tilde{A}_a\right]}{\pi^{\frac{D}{2}}\Gamma\left(\frac{D}{2}\right)\Gamma^2(\nu)\left(A_a - B_a\nu\right)^2} \int_0^\infty dx\, x^{D+2\nu-1} \frac{\bar{K}_\nu^{(b)}(x)}{\bar{I}_\nu^{(b)}(x)}, \tag{4.9}$$

and

$$\Delta\varepsilon_b^{(\mathrm{surf})} = k_D^D \left(\frac{z_a}{z_b}\right)^{2\nu} \frac{B_a\nu + A_a}{B_a\nu - A_a} f_\nu^{(b)}, \tag{4.10}$$

where we have introduced the notation

$$f_\nu^{(b)} = \frac{B_b\left[2\zeta B_b - (4\zeta - 1)\,\tilde{A}_b\right]}{2^{2\nu+D-1}\pi^{\frac{D}{2}}\Gamma\left(\frac{D}{2}\right)\nu\Gamma^2(\nu)} \int_0^\infty dx\, \frac{x^{D+2\nu-1}}{\bar{I}_\nu^{(b)2}(x)}. \tag{4.11}$$

For $|A_a| = |B_a|\nu$ it is necessary to take into account the next terms in the corresponding expansions of the Bessel modified functions for small values of the argument. The integral in Eq. (4.9) is negative for small values of the ratio A_b/B_b and is positive for large values of this ratio. As it follows from Eq. (4.10), the sign of the quantity $\Delta\varepsilon_b^{(\mathrm{surf})}$ for large interbtane separations is determined by the combination $(B_a^2\nu^2 - A_a^2)[2\zeta + (1-4\zeta)\tilde{A}_b/B_b]$ of the coefficients in the boundary conditions.

For large values of the mass with $m \gg k_D$ and $m(b-a) \gg 1$, as we see from Eq. (2.17), one has $\nu \sim m/k_D \gg 1$. Introducing a new integration variable $u = \nu y$ and using the uniform asymptotic expansions for the Bessel modified functions, to the leading order from (4.3) one receives

$$\Delta\varepsilon_j^{(\mathrm{surf})} \approx n^{(j)} \frac{2\zeta B_j - (4\zeta - 1)\tilde{A}_j}{\left[2\pi(z_b^2/z_a^2 - 1)\right]^{D/2}} \frac{(A_l + n^{(l)} m\tilde{B}_l)(mk_D)^{D/2} m\tilde{B}_j}{(A_l - n^{(l)} m\tilde{B}_l)(A_j - n^{(j)} m\tilde{B}_j)^2} e^{-2m(b-a)}, \tag{4.12}$$

where $l = a$ for $j = b$ and $l = b$ for $j = a$, and we keep $m\tilde{B}_l$ an arbitrary. As we could expect in this case the induced surface densities are exponentially suppressed. In Fig. 2 we have plotted the surface energy densities determined by Eq. (4.3) as functions on z_a/z_b and A_b/B_b for $A_a/B_a = -2$.

To discuss the physics from the point of view of a D-dimensional observer residing on the brane $y = j$, it is convenient to introduce rescaled coordinates $x_j'^{\mu}$ in accordance with $x_j'^{\mu} = e^{-k_D j} x_j^{\mu}$. With these coordinates the warp factor in the metric is equal to 1 at the brane $y = j$ and they are physical coordinates for an observer on this brane. Now after the dimensional reduction of the action, by the way similar to that in the Randall-Sundrum braneworld (see, e.g., [6]), it can be seen that D-dimensional Newton's constant G_{Dj} measured by an observer on the brane at $y = j$ is related to the fundamental $(D+1)$-dimensional Newton's constant G_{D+1} by the formula (for the gravitational equation on the brane see, e.g., [8],[60])

$$G_{Dj} = \frac{(D-2)k_D G_{D+1}}{e^{(D-2)k_D(b-a)} - 1} e^{(D-2)k_D(b-j)}. \tag{4.13}$$

Note that in the orbifolded version of the model an additional factor 2 appears in the denominator of the expression on the right. For large interbrane distances one has $G_{Da} \sim k_D G_{D+1}$, $G_{Db} \sim k_D G_{D+1} e^{(2-D)k_D(b-a)}$, and the gravitational interactions on the brane $y = b$ are exponentially suppressed. This feature is used in the Randall-Sundrum model to address the hierarchy problem. Now we will show that this mechanism also allows to obtain a naturally small cosmological constant generated by vacuum quantum fluctuations.

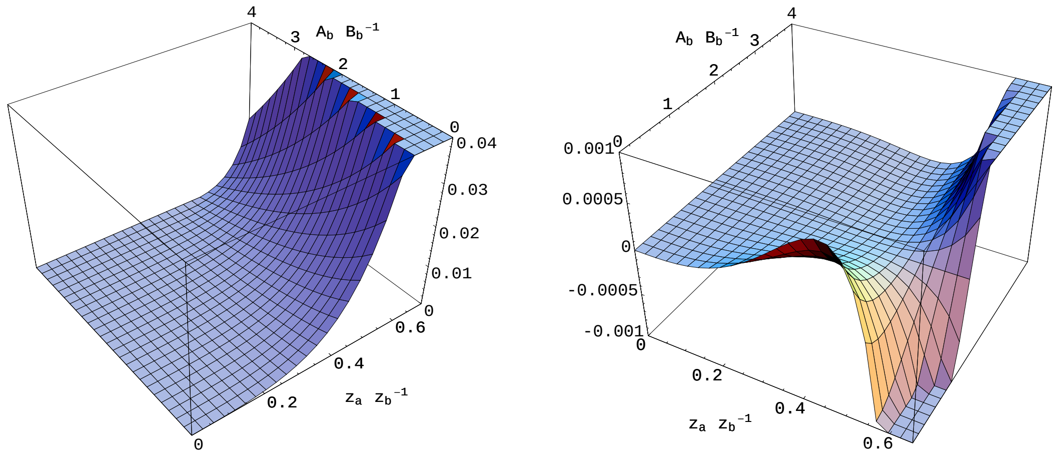

Figure 2: The surface energy densities $(z_b/z_j)^D \Delta\varepsilon^{(j)}/k_D^D$, $j = a, b$, as functions on z_a/z_b and A_b/B_b for a massless minimally coupled scalar field with $A_a/B_a = -2$ in $D = 3$ induced on the branes at $z = z_a$ (left panel) and $z = z_b$ (right panel).

The surface energy density (4.3) corresponds to the gravitational source of the cosmological constant type induced on the brane at $z = z_j$ by the presence of the second brane. Within two brane geometry discussed in this section, from the point of view of an observer living on the brane at $z = z_j$ the effective cosmological constant induced by the second brane is determined by the relation

$$\Lambda_{Dj} = 8\pi G_{Dj} \Delta\varepsilon_j^{(\mathrm{surf})} = \frac{8\pi \Delta\varepsilon_j^{(\mathrm{surf})}}{M_{Dj}^{D-2}}, \tag{4.14}$$

where M_{Dj} is the D-dimensional effective Planck mass scale for an observer on the brane. By using relation (4.13), for the numerical estimates it is convenient to present the ratio of the induced cosmological constant (4.14) to the corresponding Planck scale quantity in the brane universe in the form

$$\frac{\Lambda_{Dj}}{8\pi G_{Dj} M_{Dj}^D} = \frac{\Delta\varepsilon_j^{(\mathrm{surf})}}{k_D^D} \left(\frac{z_b}{z_j}\right)^D \left(\frac{k_D}{M_{D+1}}\right)^{\frac{D(D-1)}{D-2}} \left[\frac{D-2}{(z_b/z_a)^{D-2} - 1}\right]^{\frac{D}{D-2}}, \tag{4.15}$$

where M_{D+1} is the fundamental $(D+1)$-dimensional Planck mass, $G_{D+1} = M_{D+1}^{1-D}$. For large interbrane distances, by taking into account formulae (4.9), (4.10), one obtains the following estimate

$$\frac{\Lambda_{Dj}}{8\pi G_{Dj} M_{Dj}^D} \sim \left(\frac{z_a}{z_b}\right)^{D+2\nu} \left(\frac{k_D}{M_{D+1}}\right)^{\frac{D(D-1)}{D-2}}, \tag{4.16}$$

showing that this ratio is of the same order of magnitude for both branes. However, due to the large hierarchy between the Newton's constants on the branes, for the ratio of the induced cosmological constants one has $\Lambda_{Db}/\Lambda_{Da} \sim (z_b/z_a)^2$.

In the Randall-Sundrum $(D+1)$-dimensional braneworld the brane at $z = z_b$ corresponds to the visible brane. For large interbrane distances by taking into account Eq. (4.10), for the ratio of the induced cosmological constant (4.14) to the corresponding Planck scale quantity in the corresponding brane universe one obtains

$$\frac{\Lambda_{Db}}{8\pi G_{Db} M_{Db}^D} \approx \left(\frac{z_a}{z_b}\right)^{D+2\nu} \left(\frac{k_D}{M_{D+1}}\right)^{\frac{D(D-1)}{D-2}} \frac{B_a\nu + A_a}{B_a\nu - A_a} f_\nu^{(b)}, \tag{4.17}$$

where the function $f_\nu^{(b)}$ is defined by Eq. (4.11). As this function determines the value of the induced cosmological constant for large interbrane distances, in Figure 3 we have plotted its dependence on the ratio of the coefficients in the boundary condition on the visible brane and on the mass of the scalar field for minimally and conformally coupled cases.

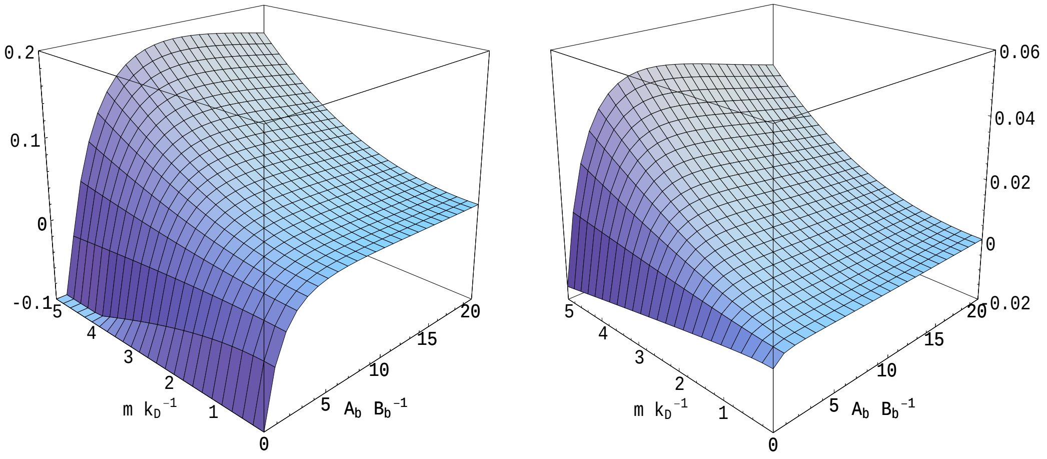

Figure 3: The quantity $f_\nu^{(b)}$ defined by Eq. (4.11) as a function on the ratio A_b/B_b and m/k_D in the model with $D = 4$ for minimally (left panel) and conformally (right panel) coupled scalar fields.

The higher dimensional Planck mass M_{D+1} and AdS inverse radius k_D are two fundamental energy scales in the $(D+1)$-dimensional AdS bulk space which in the Randall-Sundrum model are usually assumed to be of the same order, $k_D \sim M_{D+1}$ (see, e.g., [6]). In this case from Eq. (4.17) one obtains the cosmological constant which is exponentially suppressed to compared with the corresponding Planck scale quantity on the visible brane. In the original Randall-Sundrum braneworld with $D = 4$, $M_{D+1} \sim TeV$, $M_{Db} = M_{\rm Pl} \sim 10^{16}\, TeV$, to account for the observed hierarchy between the gravitational and electroweak scales, in accordance with Eq. (4.13) we need $z_b/z_a \sim 10^{16}$ (by formula (4.4) this corresponds to the interbrane distance about 37 times larger than the AdS radius k_D^{-1}). In the case of a scalar field with the mass $|m^2| \lesssim k_D^2$ (recall that on AdS bulk the parameter m^2 can also be negative), for the induced cosmological constant this leads to the estimate which is of the right order of magnitude with the value implied by the cosmological observations.

5 Energy balance

In this section we will consider the balance between the separate parts of the vacuum energy. In the region between the branes the total vacuum energy per unit coordinate volume on the branes is the sum of zero-point energies of elementary oscillators:

$$E = \frac{1}{2} \int \frac{d^{D-1}\mathbf{k}}{(2\pi)^{D-1}} \sum_{n=1}^{\infty} (k^2 + u_{\nu,n})^{1/2}, \tag{5.1}$$

where $u_{\nu,n}$ are roots of equation (2.21). The total vacuum energy in the bulk region $z_a \leq z \leq z_b$ is obtained by the integration of ${}_0^0$-component of the volume energy-momentum tensor over this region:

$$E^{(\rm vol)} = \int d^{D+1}x \, \sqrt{|g|} \langle 0 | T_0^{(\rm vol)0} | 0 \rangle. \tag{5.2}$$

Using the formula for the volume energy-momentum tensor from Ref. [31], we can see that this energy differs from (5.1) (see Ref. [49] for the discussion in general case of bulk and boundary geometries). This difference is due to the presence of the surface energy located on the branes. The surface energy per unit coordinate volume on the brane, $E^{(\mathrm{surf})}$, is related to the surface densities from Eq. (2.11) by the formula

$$E^{(\mathrm{surf})} = \sum_{j=a,b} \frac{\varepsilon_j^{(\mathrm{surf})}}{(k_D z_j)^D}. \tag{5.3}$$

Now it can be easily checked that the total vacuum energy is the sum of the volume part and the surface part:

$$E = E^{(\mathrm{vol})} + E^{(\mathrm{surf})}. \tag{5.4}$$

Expression (5.1) may be evaluated using the procedure which is basically the same as that used in Refs. [61] (see [55, 56] for reviews) for studying the Casimir effects in the geometry of spherical boundaries. Within the framework of the Randall-Sundrum braneworld, this has been done in Refs. [18, 20, 24] by the dimensional regularization method and in Ref. [22] by the zeta function technique. Refs. [18, 20, 22] consider the case of a minimally coupled scalar field in $D = 4$, and the case of arbitrary ζ and D with zero mass terms c_a and c_b is calculated in Ref. [24]. Here we briefly outline the zeta function approach in the general case. Instead of (5.1) we introduce the following zeta function

$$\zeta(s) = \mu^{s+1} \int \frac{d^{D-1}\mathbf{k}}{(2\pi)^{D-1}} \sum_{n=1}^{\infty} (k^2 + u_{\nu,n})^{-s/2}, \tag{5.5}$$

where, as above, the parameter μ with dimension of mass is introduced by dimensional reasons. Evaluating the integral over $\mathbf{k}$ one receives

$$\zeta(s) = \frac{\mu^{s+1}}{(4\pi)^{\frac{D-1}{2}}} \frac{\Gamma\left(\frac{s-D+1}{2}\right)}{\Gamma\left(\frac{s}{2}\right)} \sum_{n=1}^{\infty} u_{\nu,n}^{D-s-1}. \tag{5.6}$$

We need to perform the analytic continuation of the sum on the right of this formula to the neighborhood of $s = -1$. Transforming it into a contour integral and by deforming the contour appropriately, the total energy in the region $z_a \leq z \leq z_b$ is presented in the form

$$E = \frac{1}{2}\zeta(s)|_{s=-1} = E_{z\geq z_a}^{(a)} + E_{z\leq z_b}^{(b)} + \Delta E, \tag{5.7}$$

where $E_{z\geq z_a}^{(a)}$ is the vacuum energy in the region $z \geq z_a$ for a single brane at $z = z_a$, and $E_{z\leq z_b}^{(b)}$ is the vacuum energy in the region $z \leq z_b$ for a single brane at $z = z_b$. The interference term ΔE in this formula is finite for all nonzero values of the interbrane separation (see below, Eq. (5.16)) and the analytic continuation is needed for single brane parts only. Under the assumption $B_b \neq 0$, for the region $z \leq z_b$ the latter is given by the expression

$$E_{z\leq z_b}^{(b)} = \frac{\mu^{s+1}(4\pi)^{(1-D)/2}}{2\Gamma\left(\frac{s}{2}\right)\Gamma\left(\frac{D+1-s}{2}\right)} \int_0^{\infty} du\, u^{D-s-1} \frac{d}{du} \ln\left[\Sigma_\nu^{(I,b)}(uz_b)\right]\Big|_{s=-1}, \tag{5.8}$$

where we have introduced the notation

$$\Sigma_\nu^{(I,b)}(uz_b) = \sqrt{\frac{2\pi}{uz_b}} \frac{e^{-uz_b}}{B_b} \bar{I}_\nu^{(b)}(uz_b), \tag{5.9}$$

and, as before, $|_{s=-1}$ is understood in the sense of the analytic continuation. The expression for the energy $E^{(a)}_{z\geq z_a}$ is obtained from Eq. (5.9) by the replacement

$$\Sigma_\nu^{(I,b)}(uz_b) \rightarrow \Sigma_\nu^{(K,a)}(uz_a) = -\sqrt{\frac{2}{\pi u z_a}}\frac{e^{uz_a}}{B_a}\bar{K}_\nu^{(a)}(uz_a). \tag{5.10}$$

After the analytic continuation we can see that $E^{(b)}_{z\leq z_b}$ contains pole and finite parts,

$$E^{(b)}_{z\leq z_b} = E^{(b)}_{z\leq z_b,\mathrm{p}} + E^{(b)}_{z\leq z_b,\mathrm{f}}, \tag{5.11}$$

with

$$E^{(b)}_{z\leq z_b,\mathrm{p}} = -\frac{w_D^{(b)}(\nu)\beta_{D+1}}{z_b^D(s+1)}, \tag{5.12}$$

for the pole part, and

$$\begin{aligned} E^{(b)}_{z\leq z_b,\mathrm{f}} = & -\frac{\beta_{D+1}}{Dz_b^D}\left\{\int_0^1 du\, u^D \frac{d}{du}\ln\left(\Sigma_\nu^{(I,b)}(u)\right)\right. \\ & + \int_1^\infty du\, u^D\frac{d}{du}\left[\ln\left(\Sigma_\nu^{(I,b)}(u)\right) - \sum_{l=1}^N \frac{w_l^{(b)}(\nu)}{u^l}\right] \\ & \left. + \sum_{\substack{l=1\\ l\neq D}}^N \frac{l w_l^{(b)}(\nu)}{D-l} + D w_D^{(b)}(\nu)\left[\ln(\mu z_b) + \frac{1}{2}\psi\left(\frac{D}{2}+1\right) - \frac{1}{2}\psi\left(-\frac{1}{2}\right)\right]\right\}, \end{aligned} \tag{5.13}$$

for the finite part, with $N > D-1$. In these formulae, $w_l^{(j)}(\nu)$ are the coefficients in the asymptotic expansion of the function $\ln\left[\Sigma_\nu^{(I,j)}(u)\right]$ for large values of the argument:

$$\ln\left[\Sigma_\nu^{(I,j)}(u)\right] \sim \sum_{l=1}^\infty \frac{w_l^{(j)}(\nu)}{u^l}, \quad j=a,b. \tag{5.14}$$

These coefficients can be related to the coefficients in the similar expansions for the Bessel modified functions (see, for instance, [58]). The corresponding formulae for the energy $E^{(a)}_{z\geq z_a}$ are obtained from expressions (5.12) and (5.13) by replacements (5.10) and $w_l^{(b)}(\nu) \rightarrow (-1)^l w_l^{(a)}(\nu)$. The renormalization of the divergences in the corresponding formulae for the vacuum energies can be performed by using the brane tensions (for a detailed discussion of the renormalization procedure within the framework of the Randall-Sundrum model see, e.g., Refs. [20],[22],[23]).

As in the case of the surface energies, now we see that in the calculation of the total vacuum energy for a single brane at $z=z_a$ in odd spatial dimensions, including the contributions from L- and R-regions, the pole parts of the energies cancel out (assuming that the coefficients in the boundary conditions (2.4) on the right and left surfaces are the same) and we obtain a finite result. In particular, taking $N=D-1$, for this energy one receives

$$\begin{aligned} E^{(a)} = & -\frac{\beta_{D+1}}{Dz_a^D}\left\{\int_0^1 du\, u^D\frac{d}{du}\ln\left(\Sigma_\nu^{(I,a)}(u)\Sigma_\nu^{(K,a)}(u)\right)\right. \\ & + \int_0^1 du\, u^D\frac{d}{du}\left[\ln\left(\Sigma_\nu^{(I,a)}(u)\Sigma_\nu^{(K,a)}(u)\right) - 2\sum_{l=1}^{\frac{D-1}{2}}\frac{w_{2l}^{(a)}(\nu)}{u^{2l}}\right] \\ & \left. + 4\sum_{l=1}^{\frac{D-1}{2}}\frac{l w_{2l}^{(a)}(\nu)}{D-2l}\right\}. \end{aligned} \tag{5.15}$$

The expression on the right of this formula can be easily evaluated numerically. Note that the energy per unit physical volume on the brane is determined as $(k_D z_a)^D E^{(a)}$ and does not depend on the brane position.

Unlike to the single brane parts, the interference term ΔE in Eq. (5.7) is finite and is determined by the formula:

$$\begin{aligned}\Delta E &= -\frac{\beta_{D+1}}{D} \int_0^\infty du\, u^D \frac{d}{du} \ln \left| 1 - \frac{\bar{I}_\nu^{(a)}(uz_a)\bar{K}_\nu^{(b)}(uz_b)}{\bar{I}_\nu^{(b)}(uz_b)\bar{K}_\nu^{(a)}(uz_a)} \right| \\ &= \beta_{D+1} \int_0^\infty du\, u^{D-1} \ln \left| 1 - \frac{\bar{I}_\nu^{(a)}(uz_a)\bar{K}_\nu^{(b)}(uz_b)}{\bar{I}_\nu^{(b)}(uz_b)\bar{K}_\nu^{(a)}(uz_a)} \right| .\end{aligned} \tag{5.16}$$

Note that this part of the vacuum energy is not affected by finite renormalizations. Now let us check that this quantity obeys the standard energy balance equation. We expect that in the presence of the surface energy this equation will be in the form

$$dE = -pdV + \sum_{j=a,b} \varepsilon_j^{(\mathrm{surf})} dS^{(j)}, \tag{5.17}$$

where V is the $(D+1)$-volume in the bulk and $S^{(j)}$ is the D-volume on the brane $y=j$ per unit coordinate volume on the brane,

$$V = \int_a^b dy\, e^{-Dk_D y}, \quad S^{(j)} = e^{-Dk_D j}, \quad j = a, b, \tag{5.18}$$

In Eq. (5.17), p is the perpendicular vacuum stress on the brane and is determined by the vacuum expectation value of the $_D^D$-component of the bulk energy-momentum tensor: $p = -\langle 0|T_D^{(\mathrm{vol})D}|0\rangle$. Combining equations (5.17) and (5.18), one obtains

$$\frac{\partial E}{\partial z_j} = \frac{n^{(j)}p^{(j)} - Dk_D \varepsilon^{(\mathrm{surf})(j)}}{(k_D z_j)^{D+1}}, \tag{5.19}$$

with $p^{(j)}$ being the perpendicular vacuum stress on the brane at $y=j$. In Ref. [49] it has been shown that these stresses can be presented as sums of the self-action and interaction parts:

$$p^{(j)} = p_1^{(j)} + p_{(\mathrm{int})}^{(j)}, \quad j = a, b. \tag{5.20}$$

The first term on the right is the pressure for a single brane at $y=j$ when the second brane is absent, and $p_{(\mathrm{int})}^{(j)}$ is induced by the presence of the second brane. The latter determines the interaction forces between the branes and is defined by the formula [49]

$$\begin{aligned}p_{(\mathrm{int})}^{(j)} =& -n^{(j)} k_D^{D+1} z_j^{D+1} \beta_{D+1} \int_0^\infty du\, u^{D-1} \left[1 + DB_j \frac{2\zeta B_j + (1-4\zeta)\tilde{A}_j}{B_j^2(u^2 z_j^2 + \nu^2) - A_j^2} \right] \\ &\times \frac{\partial}{\partial z_j} \ln \left| 1 - \frac{\bar{I}_\nu^{(a)}(uz_a)\bar{K}_\nu^{(b)}(uz_b)}{\bar{I}_\nu^{(b)}(uz_b)\bar{K}_\nu^{(a)}(uz_a)} \right| .\end{aligned} \tag{5.21}$$

Assuming that relation (5.19) is satisfied for the single brane parts, for the interference parts one obtains

$$\frac{\partial \Delta E}{\partial z_j} = \frac{n^{(j)} p_{(\mathrm{int})}^{(j)} - Dk_D \Delta\varepsilon_j^{(\mathrm{surf})}}{(k_D z_j)^{D+1}}. \tag{5.22}$$

Now by taking into account expressions (4.6), (5.16), (5.21) for the separate terms in this formula, we see that this relation indeed takes place. Hence, we have checked that the vacuum energies and effective pressures on the branes obey the standard energy balance equation. Note that here the role of the surface energy is crucial and the vacuum forces acting on the brane [determined by $p_{(\mathrm{int})}^{(j)}$], in general, can not be evaluated by a simple differentiation of the total vacuum energy.

6 Conclusion

The natural appearance of AdS in a variety of situations has stimulated considerable interest in the behavior of quantum fields propagating in this background. In the present paper we have investigated the expectation value of the surface energy-momentum tensor induced by the vacuum fluctuations of a bulk scalar field with an arbitrary curvature coupling parameter satisfying Robin boundary conditions on two parallel branes in AdS spacetime. The Wightman function and the vacuum expectation value of the bulk energy-momentum tensor for this geometry are investigated in Ref. [31] (see also Ref. [30] for the case of the Randall-Sundrum braneworld). By making use the expression for the surface energy-momentum tensor from Ref. [49] and the boundary conditions on the branes, the expectation values of the surface energy density and stresses are expressed via the expectation values of the field square on the branes. As an regularization procedure for the latters we use the generalized zeta function technique, in combination with contour integral representations. Using the Cauchy's theorem on residues, we have constructed an integral representations for the zeta functions on both branes, which are well suited for the analytic continuation. These functions are presented as sums of two terms. The first ones correspond to the zeta functions for single branes when the second brane is absent. The second terms are induced by the presence of the second brane and are finite at the physical point. For the analytic continuation of the single brane zeta functions we subtract and add to the integrands leading terms of the corresponding asymptotic expansions, and present them as sums of two parts. The first one is convergent at the physical point and can be evaluated numerically. In the second, asymptotic part the pole contributions are given explicitly. As a consequence, the single brane surface Casimir energies for separate L- and R-regions contain pole and finite contributions. The remained pole term is a characteristic feature for the zeta function regularization method and has been found in the calculations of the total Casimir energy for many cases of boundary geometries. As in the case of the total vacuum energy, the renormalization of these terms can be performed by using the brane tensions. For an infinitely thin brane taking L- and R-regions together, in odd spatial dimensions the pole parts cancel and the surface Casimir energy is finite. In this case the total surface energy per unit physical volume on the brane (surface tension) does not depend on the brane position and can be directly evaluated by making use formula (3.19). The results of the corresponding numerical evaluation for minimally and conformally coupled scalar fields are presented in Figure 1. As seen from the corresponding graphs, in dependence of ratio of coefficients in the boundary condition the surface energy for a single brane can be either negative or positive. The cancellation of the pole terms coming from oppositely oriented faces of infinitely thin smooth boundaries takes place in very many situations encountered in the literature. It is a consequence of the fact that the second fundamental forms are equal and opposite on the two faces of each boundary. In even dimensions there is no such a cancellation.

The surface densities induced on the brane by the presence of the second brane are investigated in Section 4. The corresponding contributions to the zeta functions are finite at the physical point giving finite quantities for all nonzero values of the interbrane distance and are not affected by finite renormalizations. The corresponding energy densities are determined by formula (4.3) and are located on the surfaces corresponding to the region between the branes. They can also be presented in another form given by Eq. (4.6). In the limit of large AdS radius, $k_D \to 0$, from this formula the result for two parallel plates on the Minkowski bulk is recovered. For large distances between the branes, the surface densities induced by the second brane are exponentially suppressed by the factor $\exp[k_D(2\nu + D)(a - b)]$ for the brane at $y = a$ and by the factor $\exp[2\nu k_D(a - b)]$ for the brane at $y = b$. The exponential suppression also takes place in the large mass limit. From the viewpoint of an observer living on the brane at $y = j$, the D-dimensional Newton's constant is related to the higher-dimensional fundamental

Newton's constant by formula (4.13) and for large interbrane separations is exponentially small on the brane $y = b$. The corresponding effective cosmological constant generated by the second brane is determined by Eq. (4.14) and is suppressed to compared with the corresponding Planck scale quantity in the brane universe by the factor $\exp[k_D(2\nu + D)(a - b)]$, assuming that the AdS inverse radius and the fundamental Planck mass are of the same order. In the original Randall-Sundrum model with $D = 4$, for a scalar field with the mass $|m^2| \lesssim k_D^2$, and interbrane distances solving the hierarchy problem, the value of the cosmological constant on the visible brane by order of magnitude is in agreement with the value suggested by current cosmological observations without an additional fine tuning of the parameters.

The vacuum energy localized on the boundary plays an important role in the consideration of the energy balance. In Section 5 we consider the total vacuum energy in the region between the branes, evaluated as a sum of zero-point energies for elementary oscillators. It is argued that this energy differs from the energy, obtained by the integration of the bulk energy density over the region between the branes. We show that this difference is due to the presence of the surface energy located on the branes. Further we briefly outline the procedure for the regularization of the total vacuum energy by the zeta function technique. This energy is presented as a sum of single branes and interference parts. The single brane terms contain pole and finite contributions and explicit formulae are given for both these parts. In the calculations of the total vacuum energy for a single brane in odd spatial dimensions the pole parts of the energies, coming from L- and R-regions, cancel out and a finite result emerges. This energy per unit physical volume on the brane is independent of the brane position. For the geometry of two parallel branes, the interference part in the total vacuum energy is given by formula (5.16) and is finite for all nonzero values of the interbrane separation. Further, we have shown that the induced vacuum densities and vacuum effective pressures on the branes satisfy the energy balance equation (5.17) with the inclusion of the surface terms, which can also be written in the form (5.22).
